TABLES FOR THE DISTRIBUTION OF THE NUMBER OF EXCEEDANCES

by

Benjamin Epstein  
Department of Mathematics  
Wayne University

1. Introduction and Summary.

Consider a random sample of size  $n$  taken from a continuous distribution  $f(x)$ . Let another random sample, independent of the first sample and also of size  $n$ , be drawn from the same population. Let  $U_r^n$  be the random variable associated with the number of values in the second sample which exceed the  $r$ th smallest value in the first sample. Similarly let  $V_s^n$  be the random variable associated with the number of values in the second sample which exceed the  $s$ th largest value in the first sample. Due to the fact that the  $r$ th smallest value in a sample of size  $n$  is at the same time the  $s$ th largest value in the sample with  $s = n-r+1$ , it follows that

$$(1) \quad \Pr(U_r^n = x) = \Pr(V_s^n = x), \text{ where } s = n-r+1, \quad r = 1, 2, \dots, n, \text{ and} \\ x = 0, 1, 2, \dots, n.$$

The probability distribution of  $U_r^n$  (and hence of  $V_s^n$ ) is given by:

$$(2) \quad \Pr(U_r^n = x) = \binom{n-x+r-1}{r-1} \binom{n-r+x}{x} / \binom{2n}{n}, \quad x = 0, 1, 2, \dots, n.$$

Formula (2) can be proved by combinatorial methods. Details are left to

the reader. An alternative formula, derived in another way, is given in [1]. If the values of  $\Pr(U_r^n \leq x)$ , for  $x = 0, 1, 2, \dots, n-1$ ,  $r = 1(1)n$ , are written (for fixed  $n$ ) in matrix form, one notes certain useful symmetries, which can be expressed by the following identities

$$(3) \quad \Pr(U_r^n \leq x) = \Pr(U_x^n \leq r-1)$$

and

$$(4) \quad \Pr(U_r^n \leq x) + \Pr(U_{n-x+1}^n \leq n-x-1) = 1.$$

If one takes  $x = n-r$  in (4) and uses the relation (3), it is readily verified that

$$(5) \quad \Pr(U_r^n \leq n-r) = 1/2.$$

Proofs<sup>(2)</sup> of (3), (4), and (5) can be obtained by using the results of pages 257-258 of [1]. Because of these symmetries, the complete matrix can (for any fixed  $r$ ) be constructed if one knows only the quantities,  $\Pr(U_r^n \leq x)$ ,  $r = 1(1)[n/2]$ ,  $x = r-1, r, r+1, \dots, n-r-1$ . In Table 1 these values are given for  $n = 2(1)20(5)50$ .<sup>(3)</sup> To see how the complete matrix is obtained from Table 1, it is interesting to verify using (3), (4), and (5) that the complete matrix is, in the special case  $n = 5$ , given by:

---

$$(1) \quad \Pr(U_r^n \leq n) = 1 \text{ for any } n \text{ and any } r.$$

- (2) We wish to acknowledge with thanks a communication from Dr. E. J. Gumbel on this point.
- (3) The case where the two samples may be of unequal size is of practical importance. Formulae for this case and tables for selected pairs of unequal values of the sample size will appear in a subsequent report.

$x^2$	0	1	2	3	4
1	.0 <sup>2</sup> 397	.0238	.0833	.2222	.5000
2	.0238	.1032	.2619	.5000	.7778
3	.0833	.2619	.5000	.7381	.9167
4	.2222	.5000	.7381	.8968	.9762
5	.5000	.7778	.9167	.9762	.9 <sup>2</sup> 303

Table 2: Values of  $\Pr(\bar{Y}_r^5 \leq x)$

A somewhat different, but related exceedance problem, is to take two random samples of size  $n$  from a continuous distribution  $f(x)$ . Let us for convenience attach the letter  $x$  to one of the samples and the letter  $y$  to the other sample. Further let  $x_{r,n}$  and  $y_{r,n}$  be respectively the  $r$ th smallest observations in each of the samples. Let us define

$z_{r,n} = \max(x_{r,n}, y_{r,n})$ . If  $z_{r,n} = x_{r,n}$ , count the number of  $y$ 's which are  $\geq x_{r,n}$ ; if  $z_{r,n} = y_{r,n}$ , count the number of  $x$ 's which are  $\geq y_{r,n}$ . Denoting the number of exceedances as  $W_x^B$ , it is readily seen from (1) that the probability distribution of  $W_x^B$  is given by

$$(6) \quad \Pr(W_x^B = x) = 2 \left( \binom{n-r+r-1}{r-1} \binom{n-r+x}{x} \right) / \binom{2n}{n}, \quad x = 0, 1, 2, \dots, n-r.$$

It is evident from the definition that,

$$(7) \quad \Pr(W_x^B \leq x) = 1, \quad \text{for } x \geq n-r.$$

Clearly one can find the values of  $\Pr(W_x^B \leq x)$  by using Table 1. Thus,

---

(4) Since  $f(x)$  is continuous, it is assumed that  $\Pr(x_{r,n} = y_{r,n}) = 0$ .

e.g., in the special case  $n = 5$  one gets

$r^x$	0	1	2	3	4
1	.0794	.0476	.1667	.4444	1.0000
2	.0476	.2064	.5238	1.0000	
3	.1667	.5238	1.0000		
4	.4444	1.0000			
5	1.0000				

Table 3:  $\Pr(W_r^5 \leq x)$

## 2. Applications of Exceedance Theory

There are three principal uses of exceedance theory. These are:

- (a) Floods and droughts. This theory has been used by H. A. Thomas, Jr. [4] in making predictions about the occurrences of floods and droughts in the future on the basis on what is known from past data.
- (b) Non-parametric tests for slippage. The functions  $U_r^n$ ,  $V_s^n$  and  $W_r^n$  can be used to give two-sample non-parametric tests for slippage of the mean. There are close connections between the results in this paper and recent tests for slippage by Mosteller and Tukey [2,3].
- (c) Life Testing. It is a characteristic feature of life tests that data become available in order of size. Thus it becomes very natural to apply exceedance theory, which is based purely on order statistics. By so doing it is possible in many cases to shorten both the average time and average number of items destroyed in order to reach a decision as to whether or not the items in one population are in some sense superior to the items in another population.

3. Numerical Examples

Example 1: What is the probability that the third largest flood during the past 20 years will be exceeded at least once during the next 20 years? Answer. The probability is  $p = 1 - \Pr(V_3^{20} = 0) = 1 - \Pr(U_{18}^{20} = 0) = 1 - .1154 = .8846$ .

Example 2: During a period of 20 years the lowest observed annual rainfall in a certain locality was 8.6 inches. What is the probability that in the next 20 years at least two of the years have rainfall  $\leq 8.6$  inches? Answer. The probability is  $p = \Pr(U_1^{20} \leq 18) = .2436$ .

Example 3: (a one-sided test)

We are now interested in making a choice between two lots A and B. In particular we are interested in some characteristic such as life or strength where data become available in order of magnitude. Let it be known a priori that the probability density function associated with lot B is either the same as that of lot A or is displaced to the left (e.g., is inferior). Put in another way we are thinking of a case where the only relevant parameter is some measure of slippage. We wish to test the hypothesis  $H_0$  (no displacement) against the alternative  $H_1$  (B is displaced to the left of A). The Type I error is taken to be  $\leq .05$ . Let 10 items be drawn from each of the lots and placed on life test. It is decided in advance that a decision will be based on how many failures occur in the sample from B before the second failure occurs in the sample from A. The two samples are put on test simultaneously and one gets the following pattern (a denotes a failure in the sample drawn from A, b denotes a failure in the sample drawn from B): bbbabbb... The experiment is stopped at the seventh failure with the rejection of the null hypothesis. This is because  $\Pr(U_2^{10} \leq 4) = .0286 < .05$ . If, however, we had obtained a pattern like babba... we would have stopped experimentation after the fifth failure with the acceptance of  $H_0$ .

Example 4: (two-sided test). Given two lots A and B. We wish to test the null hypothesis that the life distribution of A and B are the same against the alternative that they are different. As in example 3 let 10 items be drawn at random from each of the two lots and placed on life test. It is decided in advance that our decision will be based on the statistic  $W_2^{10}$ . Suppose e.g., the failure pattern observed is aaaaabaa... , then the experiment would be terminated on the eighth trial with the rejection of the null hypothesis (on the .05 level of significance). This is because  $Pr(W_2^{10} \leq 3) = .0198$ . On the other hand a pattern like babba... would lead to acceptance of the null hypothesis on the fifth trial.

It might be remarked that fairly extensive random sampling experiments have shown that the statistics  $W_1^{10}$ ,  $W_2^{10}$ , and  $W_3^{10}$  are more effective than the run test and somewhat less effective than the Wilcoxon rank test for detecting slippage of the mean in the case where the underlying distributions are normal, all with the same variance. Since the improvement in power obtained by using  $W_2^{10}$  or  $W_3^{10}$  rather than  $W_1^{10}$  is inor in this case there are sound practical reasons for preferring  $W_1^{10}$ . Decisions based on this statistic can be made at a great saving in average time to decision as well as average number of items destroyed. It should be noted in Example 4 that if decisions were based on  $W_1^{10}$ , we would have truncated testing on the fifth trial with the rejection of  $H_0$  since  $Pr(W_1^{10} \leq 5) = .0325$ .

A detailed discussion of the points raised in the last paragraph will appear elsewhere.

#### 4. Acknowledgement.

We wish to thank John Lay for his work in computing the tables.
